Rethinking AI literacy education in higher education: Bridging risk perception and responsible adoption

Shasha Yu^{a, b, *}, Fiona Carroll^b, Barry L. Bentley^{b, c}^a School of Professional Studies, Clark University, 950 Main Street, Worcester, 01610, MA, USA^b Cardiff School of Technologies, Cardiff Metropolitan University, Llandaff Campus, Western Avenue, Cardiff, CF5 2YB, Wales, UK^c Harvard Medical School, 25 Shattuck Street, Boston, 02115, MA, USA

HIGHLIGHTS

- Explicit risks are perceived more strongly than scenario-based risks.
- Higher willingness to adopt AI is associated with lower perceived risk.
- Technical education reduces gender gaps in risks awareness but not in adoption.
- AI-related students show underappreciation of risks in scenario-based contexts.
- Findings indicate a need for contextualized AI risk education in higher education.

Scenario-based assessment

ABSTRACT

As AI becomes increasingly embedded across societal domains, understanding how future AI practitioners—particularly technology students—perceive its risks is essential for responsible development and adoption. This study analyzed responses from 139 students in Computer Science, Data Science/Data Analytics, and other disciplines using both explicit AI risk ratings and scenario-based assessments of risk and adoption willingness. Four key findings emerged: (1) Students expressed substantially higher concern for concrete, explicitly stated risks than for abstract or scenario-embedded risks; (2) Perceived risk and willingness to adopt AI demonstrated a clear inverse relationship; (3) Although technical education narrowed gender differences in risk awareness, male students reported higher adoption willingness; and (4) A form of “risk underappreciation” was observed, wherein students in AI-related specializations showed both elevated explicit risk awareness and higher willingness to adopt AI, despite lower recognition of risks in applied scenarios. These findings underscore the need for differentiated AI literacy strategies that bridge the gap between awareness and responsible adoption and offer valuable insights for educators, policymakers, industry leaders, and academic institutions aiming to cultivate ethically informed and socially responsible AI practitioners.

1. Introduction

Artificial Intelligence (AI) is reshaping modern society across sectors such as healthcare, education, transportation, and entertainment (Shaheen, 2021; Zhai et al., 2021). Its integration delivers substantial benefits—including efficiency gains, new discoveries, and improved convenience (Lee et al., 2023)—while simultaneously introducing well-documented risks such as privacy breaches, algorithmic bias, job displacement, and misuse (Yu & Carroll, 2023). Despite growing public exposure to AI, awareness of these risks remains uneven (Brauner et al.,

2023; Yu et al., 2024a), at times leading to uninformed adoption and inadequate scrutiny (Yu et al., 2024c). The rapid expansion of generative AI in both educational and professional settings has intensified the need to understand how emerging practitioners assess AI-related risks.

Within computing and engineering education, scholars emphasize that future AI practitioners require explicit preparation for ethical reasoning and responsible design practices (Archambault et al., 2024; Brown et al., 2024; Kasinidou et al., 2021b). Technology students—who will become the developers, analysts, and engineers responsible for building and governing AI systems—represent a particularly

Email address: shayu@clarku.edu (S. Yu).

consequential population. Their perceptions of AI risks shape not only their own adoption behaviors but also the decisions they will make as future professionals. However, although prior studies have examined student attitudes toward AI (Sáez-Velasco et al., 2025; Stöhr et al., 2024) and perceptions of AI's benefits and risks in educational contexts (Li et al., 2025; Tierney et al., 2025), comparatively little work has jointly examined (a) explicit risk awareness, (b) scenario-based recognition of risks in applied contexts, and (c) how these relate to willingness to adopt AI technologies. Key questions therefore persist:

- What types of AI risks are tech students most concerned about?
- Are there patterns or gaps in their understanding of AI risks that need to be addressed?
- How does their awareness of risks shape their willingness to adopt, develop, or advocate for AI technologies?
- Are there differences in the understanding of AI risks based on technical specialization?

Existing studies examine students' attitudes toward AI adoption (Sáez-Velasco et al., 2025) and their perceptions of AI's benefits and risks in educational contexts (Li et al., 2025; Tierney et al., 2025). Some works investigate general student populations (Delello et al., 2023) or center on adoption determinants rather than risk awareness (Wang et al., 2021), leaving technology students' AI risk understanding comparatively underexamined. Research in computing education and FATE further documents uneven recognition of fairness and safety issues in real-world systems (Archambault et al., 2024; Brown et al., 2024; Kasinidou et al., 2021a,b; Pierson, 2017), underscoring the need for empirical work that situates risk awareness as a core construct in understanding responsible AI adoption.

This gap limits the development of targeted AI literacy programs that prepare students to navigate and mitigate risks responsibly. To address this need, the present study investigates the current state of AI risk awareness among technology students, examines patterns in explicit and scenario-based assessments, and analyzes how these perceptions shape willingness to adopt AI technologies. By integrating both explicit and scenario-based assessments, the study also provides a more comprehensive view of how students articulate risks in the abstract and how they recognize them in applied contexts.

By uncovering these relationships, this work seeks to inform curriculum design and policy development aimed at fostering responsible AI use and development. Ultimately, the study contributes to bridging the gap between rapid AI innovation and informed, ethical practice.

2. Background

2.1. AI risks and challenges

A growing body of research highlights the multifaceted risks associated with AI systems across technical, ethical, and societal dimensions. Concerns about privacy and data security are among the most frequently discussed, particularly as AI technologies increasingly rely on large-scale personal data and often enable secondary uses beyond individuals' awareness (Manikonda et al., 2018; Naudé, 2020; Yu et al., 2023). Alongside privacy issues, scholars have extensively documented how algorithmic systems reproduce or even amplify social biases, leading to unfair outcomes in high-stakes settings such as hiring, lending, or policing (Albaroudi et al., 2024; Raghavan et al., 2020; Roselli et al., 2019). Technical vulnerabilities also represent an important class of risks: adversarial attacks and other forms of system manipulation can compromise the reliability of AI models deployed in critical domains (Chen et al., 2019; Manikonda et al., 2018).

Beyond these technical concerns, AI's broader societal implications have also drawn increasing scholarly attention. Automation-related job displacement continues to raise questions about economic inequality and the need for large-scale workforce adaptation (Rawashdeh, 2025; Yu & Carroll, 2023). The rapid spread of misinformation—including

deepfakes and synthetic media—illustrates how AI can be leveraged to distort public discourse and manipulate public opinion (Agarwal et al., 2020; Aïmeur et al., 2023; Al-Asadi & Tasdemir, 2021). In parallel, the expansion of AI-enabled autonomous weapons has intensified ethical and accountability debates, especially regarding the delegation of lethal decision-making to non-human agents (Gómez de Ágreda, 2020; Yu & Carroll, 2022a).

Lack of transparency further complicates responsible AI deployment. "Black-box" systems limit users' and regulators' ability to understand or contest automated decisions, raising particular concerns in areas such as criminal justice and healthcare (Bernal & Mazo, 2022; Larsson & Heintz, 2020; Von Eschenbach, 2021). These transparency challenges intersect with a broader set of ethical issues—including autonomy, consent, and civil liberties—that scholars have argued are central to assessing the real-world impact of AI technologies (Benzinger et al., 2023; Saheb, 2023; Stahl & Stahl, 2021). AI systems also pose psychological and behavioral risks, influencing creativity, critical thinking, social interaction, and exposure to diverse perspectives through personalization and algorithmic filtering (Park & Park, 2024; Torres et al., 2024; Yu et al., 2024b; Zhai et al., 2024).

Finally, researchers have emphasized that AI has the potential to exacerbate existing social inequalities by embedding structural disadvantages present in training data or institutional contexts (Capraro et al., 2024; Yu & Carroll, 2022b; Zajko, 2022). These concerns intersect with the broader risk of AI misuse—ranging from targeted disinformation campaigns to surveillance and political manipulation—enabled by the scale and efficiency of contemporary AI systems (Anderljung et al., 2024; Yu & Carroll, 2022a).

Together, these strands of scholarship identify a comprehensive set of AI-related risks that inform the conceptual framing of this study and underpin the explicit AI risk awareness items used in the survey instrument.

2.2. AI risk perception and adoption

Risk perception often diverges between abstract judgments and applied, context-dependent decisions. Foundational work shows that framing, salience, and bounded rationality shape how individuals weigh risks and benefits (Kahneman & Tversky, 2013; Slovic, 2016). Technology-adoption research similarly models how perceived risk moderates intention (Ajzen, 1991; Venkatesh et al., 2003). In educational settings, studies report mixed patterns in students' AI risk judgments and adoption tendencies, with gaps between perceived usefulness and concerns about accuracy, bias, and learning effects (Crockett et al., 2020; Oc et al., 2024; Schei et al., 2024). These literatures motivate our use of both explicit and scenario-based measures: the former elicits articulated concerns about named risks; the latter probes applied recognition when risks are not made salient a priori, which prior research suggests can surface different judgments (Kahneman & Tversky, 2013; Slovic, 2016).

2.3. AI literacy education in higher education

Universities increasingly incorporate ethical and societal dimensions into computing curricula, yet implementations vary and often emphasize principles over applied risk judgment (Brown et al., 2024). Empirical studies show that while students can articulate aspects of fairness, accountability, and transparency, recognition of risks in realistic systems is uneven and sensitive to disciplinary identity and context (Archambault et al., 2024; Kasinidou et al., 2021a,b; Pierson, 2017). Policy frameworks likewise foreground responsible AI and critical AI literacy (European Union, 2024; UNESCO, 2021), but evidence-based guidance on integrating scenario-based risk recognition into technical programs remains limited. This background motivates curricula that combine explicit instruction with applied, scenario-centered activities to strengthen transfer from concepts to practice (Archambault et al., 2024; Kasinidou et al., 2021b).

2.4. AI risk: the missing piece of a tech curriculum

Although AI perceptions and adoption have been widely studied, most existing work examines the general public or broad student populations rather than technology students (Crockett et al., 2020; Sáez-Velasco et al., 2025; Tierney et al., 2025). Prior studies often highlight general attitudes toward AI and concerns such as rapid technological change or unemployment, but they rarely assess concrete risk domains such as bias, privacy, or misuse in technically trained groups (Ghotbi & Ho, 2021; Jeffrey, 2020). Research on ChatGPT adoption focuses on usability and credibility while overlooking students' awareness of potential risks (Masa'deh et al., 2024). As a result, relatively less is known about how different dimensions of AI risk awareness relate to students' willingness to adopt or develop AI systems.

This gap is important because technology students are the future developers, engineers, and decision-makers who will influence the ethical direction of AI (Yu et al., 2024a). Understanding their risk awareness is essential for clarifying how such awareness shapes responsible adoption and for determining whether students are prepared to incorporate ethical considerations into system design. Addressing this gap requires empirical studies and educational models that explicitly connect risk perception, adoption behavior, and ethical development practices (Floridi & Floridi, 2010; Mittelstadt, 2019).

This study responds to this need by examining technology students' awareness of a range of AI risks and their willingness to adopt AI technologies. The findings are intended to support AI ethics education and curriculum design that better prepares students for responsible AI development.

3. Methodology

3.1. Research design

This study utilized a cross-sectional, mixed-methods survey to investigate technology students' awareness of AI risks and their willingness to adopt AI technologies. The instrument contained four sections: demographic characteristics, explicit AI risk awareness (quantitative), scenario-based evaluation (quantitative), and a short set of open-ended questions (qualitative) designed to elicit students' broader views on AI, perceived risks, and expectations for AI risk education. The full survey instrument is provided in the Supplementary Material.

The present manuscript analyzes only the quantitative components, which provide structured measures of explicit and scenario-based risk awareness and adoption willingness. The qualitative responses will be examined and reported in a separate manuscript, where they will offer complementary insights into students' interpretations of AI risks and their perspectives on educational needs.

3.2. Sample and participants

This study targeted students and recent graduates (within one year) enrolled in AI/ML-related graduate programs (e.g., Computer Science, Data Science, Data Analytics) at a private university in the United States. These programs include structured coursework in artificial intelligence and machine learning and therefore provide access to students with substantial exposure to AI technologies.

Participants were recruited through multiple channels: (1) distribution of the anonymous Qualtrics survey link during class sessions with instructor permission, (2) the university's SONA Research Participation System, which allowed eligible volunteers to complete the study for course credit, (3) direct email invitations sent to students in the target programs, and (4) voluntary snowball sampling in which participants shared the anonymous survey link with peers. All data were collected online, and no referral incentives were offered.

A total of 189 responses were recorded between November 19, 2024, and February 19, 2025. After removing 50 incomplete or inconsistent submissions, and with no exclusions based on demographic

characteristics, 139 valid responses remained. Of these, 116 participants were enrolled in AI-focused programs (Computer Science: $n = 48$; Data Science/Data Analytics: $n = 68$). An additional 23 respondents were obtained through snowball sampling from programs with varying degrees of AI exposure, including Information Technology, Human-Computer Interaction, Interactive Media, Game Design, Psychology, and Biology. These comparative groups were included to examine how differences in formal AI training relate to risk perception and adoption patterns.

Throughout this manuscript, "CS" refers to Computer Science, "DS/DA" refers to Data Science or Data Analytics, and "Other" refers to interdisciplinary or non-technical fields represented in the sample.

Demographic profile. The sample was predominantly young, with 63.3% aged 18–24 and 34.5% aged 25–34, and 2.2% aged 35–44. Gender distribution was nearly balanced, with 51.1% identifying as female and 48.9% as male. The majority identified as Asian (77.7%), followed by White or Caucasian (10.8%), Hispanic or Latino (4.3%), Black or African American (2.2%), Mixed or Multiple Ethnicities (2.9%), and 2.2% who preferred not to disclose. Most participants were current graduate students (Master's or PhD, 75.5%), with undergraduates comprising 21.6%; recent graduates and working professionals formed a small minority. By specialization, 48.9% reported Data Science/Data Analytics, 34.5% Computer Science, and 16.5% other fields. Regarding experience, 47.5% reported 1–3 years in the technology field, 28.1% less than one year, 21.6% 4–6 years, and 2.9% more than 7 years. Self-rated AI knowledge was generally high: 46.0% moderate, 19.4% proficient, 6.5% expert, 24.5% basic, and 3.6% no understanding. See Table 2 for full details.

3.3. Materials and measures

The survey instrument consisted of four sections: (a) seven demographic items; (b) one matrix-style item assessing explicit awareness across twelve AI risk domains; (c) ten scenario-based items, each measuring both perceived risk and willingness to adopt the technology; and (d) six open-ended qualitative questions, which are analyzed in a separate manuscript. One attention-check item was included to ensure response quality.

Explicit AI Risk Awareness. Participants rated their concern for 12 explicitly named AI risk domains (1 = Not concerned at all, 5 = Very concerned). These domains reflect widely documented categories of AI-related risks across AI ethics, governance, and HCI scholarship.

Scenario-Based Risk Awareness and Adoption Willingness. Ten realistic AI applications were presented without naming the underlying risks. For each application, participants rated (a) perceived risk and (b) willingness to adopt the system (1 = Not at all, 5 = Very). This design draws on research showing that risk judgments differ when individuals evaluate concrete contexts rather than abstract descriptions (Kahneman & Tversky, 2013; Slovic, 2016). Applications included hiring platforms, healthcare diagnostics, financial advisory tools, public surveillance, manufacturing automation, personalized learning, and smart-home systems.

Table 1 provides an overview of how the twelve explicit AI risk domains correspond to the ten scenario-based applications. This mapping clarifies the conceptual alignment between explicit risk categories and their applied manifestations.

3.4. Procedure

The survey was administered online via Qualtrics, ensuring anonymity and data security. Participants provided informed consent through an electronic page detailing the study's purpose, voluntary nature, and confidentiality. Those declining consent were redirected to a closing page. In-class participants could opt for an alternative task, and SONA participants received course credits. A quality check question identified inattentive responses.

Table 1
Mapping of explicit AI risk domains to scenario-based survey items.

Risk domain	Scenario example (Survey item)
General AI risks	No direct scenario counterpart
Privacy/Data security	Smart-home assistant learning user habits (Q13)
Bias/Fairness	Job-matching platform ranking applicants (Q14)
Security vulnerabilities	AI financial advisory system analyzing spending patterns (Q15)
Job displacement	AI-driven automation in manufacturing (Q16)
Misinformation/Manipulation	AI-curated personalized news feeds (Q17)
Autonomous weapons	Autonomous drones used for automated threat response (Q18)
Transparency issues	AI diagnostic tool predicting medical conditions (Q19)
Ethical implications	AI-enabled public surveillance systems (Q20)
Psychological/Cognitive impacts	AI assistant managing tasks and routines (Q21)
Social inequalities	Adaptive learning platform personalizing content (Q22)
Misuse/Abuse	No direct scenario counterpart

Note. Scenario descriptions correspond to Survey Items Q13–Q22 in Supplementary Material. Supporting literature for each explicit risk domain: privacy/data security (Manikonda et al., 2018; Naudé, 2020; Yu et al., 2023); bias/fairness (Albaroudi et al., 2024; Raghavan et al., 2020; Roselli et al., 2019); security vulnerabilities (Chen et al., 2019; Manikonda et al., 2018); job displacement (Rawashdeh, 2025; Yu & Carroll, 2023); misinformation (Agarwal et al., 2020; Aimeur et al., 2023; Al-Asadi & Tasdemir, 2021); autonomous weapons (Gómez de Ágreda, 2020; Yu & Carroll, 2022a); transparency (Larsson & Heintz, 2020; Von Eschenbach, 2021); ethical implications (Benzinger et al., 2023; Saheb, 2023; Stahl & Stahl, 2021); psychological/cognitive impacts (Park & Park, 2024; Torres et al., 2024; Yu et al., 2024b; Zhai et al., 2024); social inequalities (Capraro et al., 2024; Yu & Carroll, 2022b; Zajko, 2022). General AI risks and Misuse/Abuse appear only as explicit items because they represent broad, cross-cutting concerns that do not map cleanly to a single application context.

This study was approved by the Institutional Review Board at Clark University (Protocol No. 701). All participants provided informed consent prior to participation. No personally identifiable information was collected.

3.5. Validation

The instrument underwent a two-stage validation process prior to deployment. First, three faculty members with expertise in AI ethics and human-computer interaction reviewed all items for clarity, relevance, and completeness. Their feedback informed revisions to item wording and alignment across risk domains. Second, a small cognitive pilot with 12 technology students was conducted to evaluate item comprehension, survey flow, and response burden. Minor adjustments were made based on participants' comments before releasing the final instrument.

3.6. Data analysis

Quantitative data were analyzed using SPSS (v29). Data preparation included screening for completeness and removal of patterned or low-quality responses. Normality was assessed using Shapiro-Wilk tests. Reliability of the survey scales was evaluated using Cronbach's alpha. Descriptive statistics were calculated for all key variables.

Group comparisons by gender and specialization were conducted using independent-samples t-tests and one-way ANOVA for normally distributed variables, and Mann-Whitney U and Kruskal-Wallis tests for variables violating normality assumptions. This selection ensures that the statistical tests align appropriately with the distributional characteristics of each variable.

The relationship between risk awareness and adoption willingness was assessed using Pearson or Spearman correlation coefficients, depending on normality. Detailed results of reliability analysis, descriptive statistics, and inferential tests are reported in the Results section.

4. Results

4.1. Demographic overview

Table 2 summarizes the demographic characteristics of the final sample ($N = 139$), including age, gender, ethnicity, student status, specialization, years of experience, and self-rated AI knowledge. Descriptive information is further detailed in Section 3.2. These distributions provide important contextual information for interpreting subsequent analyses.

4.2. Reliability and descriptive statistics

Table 3 reports reliability and descriptive statistics for the three composite scales. All scales demonstrated acceptable to excellent reliability

Table 2
Demographic information of participants ($N = 139$).

	Count	%
Age		
18–24 years	88	63.3
25–34 years	48	34.5
35–44 years	3	2.2
Gender		
Male	68	48.9
Female	71	51.1
Ethnicity		
Asian	108	77.7
Black or African American	3	2.2
Hispanic or Latino	6	4.3
White or Caucasian	15	10.8
Mixed or Multiple Ethnicities	4	2.9
Prefer not to say	3	2.2
Status		
Current Undergraduate Student	30	21.6
Current Graduate Student	105	75.5
Recent Graduate	3	2.2

Table 3
Reliability and descriptive statistics for survey scales.

Scale	Explicit risk	Scenario risk	Adoption willingness
Items	12	10	10
Cronbach's α	0.93	0.88	0.86
Mean (SD)	3.70 (0.29)	3.10 (0.35)	3.40 (0.28)
Item mean range	2.99–4.01	2.39–3.46	2.95–3.86
Inter-item correlations	0.30–0.76	0.18–0.66	0.09–0.64
Item-total correlations	0.50–0.77	0.48–0.70	0.39–0.68

(Explicit: $\alpha = 0.93$; Scenario-based: $\alpha = 0.88$; Adoption willingness: $\alpha = 0.86$). Composite mean scores were used for all subsequent analyses.

Effect sizes (Cohen's d for t -tests and r for non-parametric tests) were computed to complement p -values and provide estimates of practical significance.

4.3. Comparative analysis

Comparisons were conducted across genders and academic specialization for explicit awareness, scenario-based awareness, and adoption willingness.

4.3.1. Explicit AI risk awareness

Descriptive patterns across risk categories by gender and specialization are presented in Table 4. Visual patterns of specialization differences are further illustrated in Fig. 1, which highlights higher explicit risk awareness among CS and DS/DA students relative to the Other group.

Explicit AI risk awareness showed no gender difference, $U = 2315.50$, $p = 0.678$, $d = 0.14$, 95% CI $[-0.198, 0.468]$.

Specialization differences were significant, Kruskal–Wallis $\chi^2(2) = 13.91$, $p < 0.001$. Post-hoc comparisons indicated: CS > Other ($p < 0.001$, $r = 0.41$, 95% CI $[0.018, 0.191]$); DS/DA > Other ($p = 0.014$, $r = 0.26$, 95% CI $[0.004, 0.179]$).

4.3.2. Scenario-based AI risk awareness

Scenario-based risk ratings for each application context are shown in Table 5. These results indicate substantial variability across scenarios but limited differences across demographic groups.

Gender difference: $t(137) = -0.23$, $p = 0.819$, $d = -0.06$, 95% CI $[-0.390, 0.275]$.

Specialization: non-significant, Kruskal–Wallis $\chi^2(2) = 3.83$, $p = 0.148$, $\eta^2 = 0.028$, 95% CI $[-0.015, 0.078]$.

4.3.3. Scenario-based adoption willingness

Fig. 2 provides a comparison of scenario-specific risk awareness and adoption willingness across all ten applications, illustrating the inverse trend between perceived risk and willingness to adopt.

Scenario-level willingness-to-adopt scores are reported in Table 6. Fig. 3 provides a visualization of group differences, demonstrating that CS and DS/DA students exhibit notably higher adoption willingness than students from other fields.

Gender difference present: $t(137) = 2.02$, $p = 0.046$, $d = 0.34$, 95% CI $[0.007, 0.677]$.

Specialization differences are significant: ANOVA $F(2, 136) = 9.85$, $p < 0.001$, $\eta^2 = 0.127$, 95% CI $[0.035, 0.226]$.

4.3.4. Explicit vs. scenario-based AI risk awareness

Results of the Wilcoxon signed-rank tests comparing explicit and scenario-based risk ratings are presented in Table 7. These findings confirm consistent and statistically significant differences between explicit and contextualized evaluations across nearly all matched domains.

Explicit awareness ($M = 3.70$) significantly exceeded scenario-based awareness ($M = 2.98$) for nearly all risks, with largest effects for psychological impacts and social inequalities.

5. Discussion

Before interpreting the findings, it is important to note that the study's cross-sectional design permits only correlational inferences; causal relationships between AI risk perception and adoption willingness cannot be established.

5.1. Key findings

5.1.1. Explicit risks elicit stronger concern than scenario-based risks

The results reveal a critical divergence in technology students' AI risk perception: explicitly stated risks elicit substantially stronger concern than risks embedded within specific application scenarios. A clear example appears in the domain of privacy: students rated explicit privacy/data security risks highly ($M = 3.98$), yet their concern declined markedly ($M = 3.14$) when the same risk was embedded in a realistic smart-home scenario. Across the full sample, the overall mean of explicit AI risk ratings was 3.70, notably higher than the 3.10 observed for scenario-based AI risk ratings.

These findings suggest that students recognize and articulate AI risks more strongly when risks are directly named and conceptually framed, a pattern consistent with research showing that abstract descriptions can activate higher-level evaluative reasoning (Trope & Liberman, 2010). However, this awareness weakens when those same risks are presented in concrete, operational contexts. In short, explicit risk knowledge does not fully transfer to contextualized risk recognition, highlighting a gap between abstract understanding and applied judgment.

5.1.2. Perceived risk and adoption willingness are inversely related

The results provide strong evidence for an inverse relationship between perceived contextual risk and willingness to adopt AI technologies. Across all scenarios, students showed the lowest adoption willingness in domains they perceived as high-risk—most notably autonomous weapons ($M_{\text{risk}} = 3.45$, $M_{\text{adopt}} = 2.95$) and misinformation/manipulation ($M_{\text{risk}} = 3.29$, $M_{\text{adopt}} = 3.17$). In contrast, the highest adoption willingness occurred in domains perceived as lower-risk, such as psychological impacts ($M_{\text{risk}} = 2.38$, $M_{\text{adopt}} = 3.83$) and social inequalities ($M_{\text{risk}} = 2.43$, $M_{\text{adopt}} = 3.86$). This consistent pattern demonstrates that adoption judgments are shaped less by general attitudes toward AI and more by scenario-specific risk cues.

Taken together, the findings show that lower perceived risk reliably predicts greater willingness to adopt AI, even within the same student population and using parallelized scenario formats. This inverse association highlights the need for AI literacy and ethics education to incorporate contextualized risk assessments rather than relying solely on general or abstract discussions of AI safety.

5.1.3. Education equalizes risk awareness but gender differences persist in adoption

The results show that formal technical education effectively equalizes gender differences in AI risk perception. Male and female students demonstrated statistically equivalent levels of explicit risk awareness ($p = 0.678$) and scenario-based risk awareness ($p = 0.819$), indicating that domain-specific instruction provides a shared framework for evaluating AI-related harms.

Despite this convergence in risk perception, a clear behavioral divergence emerged. Male students reported significantly higher willingness to adopt AI technologies than female students ($M_{\text{male}} = 3.55$ vs. $M_{\text{female}} = 3.26$, $p = 0.046$, $d = 0.34$). This suggests that equalizing cognitive understanding of risks does not necessarily translate into equal adoption behavior.

This dissociation between awareness and behavior aligns with prior research showing that gender differences in uncertainty tolerance, trust, and perceived behavioral control can influence technology-related decisions (Byrnes et al., 1999; Gefen & Straub, 1997; Venkatesh et al., 2003). Taken together, these findings highlight that while technical education may narrow gender gaps in evaluative judgments, it does not eliminate

Table 4Mean (SD) of explicit AI risk awareness by gender and specialization ($N = 139$).

Risk category	Male	Female	CS	DS/DA	Other	Total
General AI risks	3.04 (1.20)	2.93 (1.19)	3.02 (1.30)	3.09 (1.09)	2.61 (1.23)	2.99 (1.19)
Privacy/data security	4.19 (1.03)	3.77 (1.31)	4.25 (1.18)	3.97 (1.04)	3.43 (1.50)	3.98 (1.20)
Bias/fairness	3.35 (1.09)	3.39 (1.29)	3.56 (1.40)	3.38 (1.05)	2.96 (1.07)	3.37 (1.19)
Security vulnerabilities	3.87 (1.11)	3.80 (1.20)	4.10 (1.13)	3.84 (1.09)	3.26 (1.21)	3.83 (1.15)

**Fig. 1.** Explicit AI risk awareness by academic specialization. CS and DS/DA students showed significantly higher scores than the Other group.

underlying psychological or sociocultural factors that shape willingness to adopt AI. As such, AI literacy initiatives should complement technical instruction with strategies that address these behavioral dimensions to support equitable engagement with AI technologies.

5.1.4. Specialization differences reveal evidence of applied risk underappreciation

A clear pattern emerged when comparing AI-related specializations with students from non-technical fields. Computer Science (CS) and Data Science/Data Analytics (DS/DA) students demonstrated higher explicit

AI risk awareness than students in the “Other” group, consistent with their stronger curricular exposure to AI systems. However, these same CS and DS/DA students did not show correspondingly higher recognition of risks when evaluating scenario-based applications, where their average scenario-awareness scores were comparable to or only marginally higher than those of non-technical peers.

Despite this parallel in scenario-based risk perception, CS and DS/DA students expressed substantially greater willingness to adopt AI technologies across nearly all application contexts. Students from non-technical fields, by contrast, showed markedly lower

Table 5Mean (SD) of scenario-based AI risk awareness by gender and specialization ($N = 139$).

Risk category	Male	Female	CS	DS/DA	Other	Total
Personal privacy	2.96 (1.43)	3.32 (1.20)	3.13 (1.48)	3.34 (1.30)	2.22 (1.09)	3.14 (1.33)
Bias	3.12 (1.47)	3.08 (1.42)	3.25 (1.60)	3.07 (1.34)	2.87 (1.39)	3.10 (1.44)
Security vulnerability	3.09 (1.32)	3.06 (1.34)	3.35 (1.36)	2.81 (1.34)	3.26 (1.10)	3.07 (1.33)
Job displacement	2.79 (1.40)	2.85 (1.25)	3.02 (1.42)	2.76 (1.33)	2.57 (1.04)	2.82 (1.32)
Misinformation	3.41 (1.40)	3.18 (1.41)	3.75 (1.28)	3.07 (1.40)	3.00 (1.48)	3.29 (1.40)
Autonomous weapons	3.40 (1.39)	3.49 (1.42)	3.54 (1.44)	3.32 (1.32)	3.61 (1.41)	3.45 (1.37)
Transparency	3.04 (1.40)	3.28 (1.39)	3.38 (1.38)	2.85 (1.39)	3.65 (1.27)	3.17 (1.39)
Misuse/abuse	2.76 (1.39)	3.03 (1.43)	2.88 (1.44)	2.63 (1.38)	3.74 (1.36)	2.90 (1.41)
Psychological impacts	2.44 (1.30)	2.32 (1.19)	2.38 (1.33)	2.29 (1.23)	2.65 (1.07)	2.38 (1.24)
Social inequalities	2.47 (1.38)	2.39 (1.22)	2.69 (1.52)	2.21 (1.17)	2.57 (1.08)	2.43 (1.30)
Composite Score	2.96 (0.99)	3.00 (0.91)	3.14 (1.05)	2.83 (0.90)	3.11 (0.83)	2.98 (0.95)

Fig. 2. Scenario-based risk awareness and adoption willingness across application contexts. A clear inverse relationship appears: scenarios rated as higher risk consistently show lower willingness to adopt, whereas lower-risk scenarios show higher willingness.

Fig. 3. Scenario-based adoption willingness by academic specialization. CS and DS/DA students reported significantly higher willingness than students in other disciplines.

adoption willingness, even when their scenario-based risk assessments were similar. This divergence suggests that technical specialization strengthens confidence and perceived control over AI systems, which in turn elevates willingness to adopt AI regardless of contextualized risk cues.

Taken together, these results point to a form of *risk underappreciation* among students in AI-related fields: they exhibit high explicit awareness of AI risks yet demonstrate muted sensitivity to those same risks when embedded in applied scenarios, while simultaneously showing strong enthusiasm for adoption. A plausible mechanism underlying this pattern is that greater domain familiarity can increase perceived control and reduce sensitivity to potential harms, a tendency documented in research showing that expertise often promotes overconfidence and higher risk-taking (Hilary & Menzly, 2006; Said et al., 2023). The present findings extend this work by providing quantitative evidence of risk underappreciation within the context of university-level AI education.

5.2. Implications and practical recommendations

The four key findings of this study collectively reveal several important implications for AI education, curriculum design, and

responsible AI practice. These implications extend beyond the empirical patterns reported earlier and point to concrete opportunities for strengthening students' ability to evaluate and engage with AI systems responsibly.

Table 6

Scenario-based AI risk awareness and adoption willingness ($N = 139$).

Risk type	Risk awareness		Adoption willingness	
	Mean	SD	Mean	SD
Personal privacy	3.14	1.33	3.44	1.19
Bias	3.10	1.44	3.31	1.23
Security vulnerability	3.07	1.33	3.22	1.25
Job displacement	2.82	1.32	3.55	1.22
Misinformation	3.29	1.40	3.17	1.32
Autonomous weapons	3.45	1.37	2.95	1.41
Transparency	3.17	1.39	3.28	1.30
Misuse/abuse	2.90	1.44	3.42	1.31
Psychological impacts	2.38	1.24	3.83	1.15
Social inequalities	2.43	1.30	3.86	1.21

Table 7

Wilcoxon signed-rank test: Explicit vs. scenario-based AI risk awareness.

Risk/Scenario	Z	p
Privacy in automation	-5.409	<0.001
Bias in hiring	-1.822	0.068
Security in banking	-5.074	<0.001
Job displacement in manufacturing	-5.858	<0.001
Manipulation in social media	-4.616	<0.001
Autonomous weapons in drones	-2.211	0.027
Transparency in healthcare	-3.980	<0.001
Misuse in mass surveillance	-6.061	<0.001
Psychological impacts of assistants	-7.200	<0.001
Social inequalities in education	-6.730	<0.001

In addition to these empirical findings, the study also contributes to broader work on AI risk perception and AI literacy. First, it offers a combined analysis of explicit and scenario-based AI risk awareness within the same population, enabling a direct comparison of articulated versus contextualized judgments—an approach that remains relatively uncommon in existing research. Second, it provides empirical evidence of how perceived contextual risk relates to adoption willingness across different application domains. Third, it highlights how gender and disciplinary identity shape adoption behavior even when risk awareness itself is comparable. Together, these contributions help refine theoretical understanding of AI risk perception and guide the development of more effective AI risk education strategies.

1. strengthening transfer between abstract risk knowledge and applied contexts

Section 5.1.1 showed that students recognize AI risks more strongly when they are explicitly labeled than when the same risks are embedded in realistic scenarios. This gap suggests that existing AI curricula may succeed in conveying conceptual terminology but fall short in preparing students to detect risks in operational settings. To address this disconnect, educational programs should integrate scenario-based reasoning throughout instruction—for example, by embedding case analyses, incident walkthroughs, and structured reflection exercises that require students to identify risks without being prompted by explicit labels. These strategies can support the transfer of abstract risk knowledge into applied judgment, a capacity essential for responsible AI development.

2. embedding contextualized risk evaluation into AI literacy

Section 5.1.2 demonstrated that adoption willingness closely follows contextual risk perception, highlighting the importance of teaching students how to evaluate risks not just at the conceptual level but within specific application domains. To cultivate more calibrated decision-making, AI ethics modules should incorporate domain-specific exemplars across health, security, education, entertainment, and workplace contexts. Asking students to articulate both the potential harms and justifications for adoption in each context can strengthen their ability to weigh domain-relevant trade-offs and avoid over-reliance on general attitudes toward AI.

3. addressing behavioral disparities through psychological and sociocultural support

Although Section 5.1.3 showed that technical education equalized gender differences in risk perception, it also revealed that gender gaps persist in adoption behaviors. This indicates that cognitive understanding alone is insufficient for equitable engagement. AI curricula should therefore integrate interventions that address psychological and sociocultural factors shaping adoption decisions. Activities that build self-efficacy, reduce uncertainty aversion, and strengthen calibrated trust in AI systems may help reduce gender-linked behavioral disparities. Importantly, such interventions should be framed not as remediation

but as part of a broader commitment to supporting diverse forms of engagement with AI.

4. expanding AI literacy beyond technical majors to counteract overconfidence and vulnerability

Section 5.1.4 highlighted a dual challenge: students in AI-related majors demonstrate strong explicit awareness yet show muted sensitivity to contextualized risks and an elevated willingness to adopt AI technologies. Meanwhile, students in non-technical fields show lower adoption willingness despite comparable scenario-based awareness. These patterns indicate that both groups would benefit from tailored educational strategies. For technical majors, instruction should emphasize critical self-reflection and highlight the limits of expertise to reduce overconfidence and mitigate forms of risk underappreciation. For non-technical students, AI literacy programs should focus on building foundational understanding and confidence, ensuring they are not marginalized in technology discourse or decision-making.

5. building institution-level frameworks for responsible AI education

Across Sections 5.1.1–5.1.4, a consistent theme emerges: students require structured opportunities to integrate conceptual understanding, contextual reasoning, and reflective judgment. Institutions can support this integration by adopting program-wide frameworks that map AI risk competencies across curricula, ensuring that explicit instruction, scenario-based reasoning, and reflective activities appear throughout a student's academic trajectory. Periodic needs assessments, informed by student feedback and evolving AI technologies, can help institutions adapt AI risk education to diverse learner profiles and emerging societal challenges.

5.3. Limitations of the study

While this study provides meaningful insights into technology students' AI risk awareness and adoption behavior, several limitations should be acknowledged to contextualize the findings.

First, the data were collected from a single private university in the United States, which limits generalizability beyond similar institutional and disciplinary contexts. Participation was voluntary, which may have attracted students with higher interest in or familiarity with AI. As a result, the levels of risk awareness and adoption willingness observed in this sample may not fully reflect those of the broader student population.

Second, although the sample included students from Computer Science, Data Science/Data Analytics, and a range of other majors, the "Other" group was comparatively small. This limits the ability to draw strong conclusions about non-technical fields and constrains the interpretation of disciplinary differences. Future research with more balanced representation across academic disciplines would strengthen the robustness of these comparisons.

Third, the study relied on self-reported measures of risk perception, self-assessed AI knowledge, and adoption intentions. Such measures are susceptible to social desirability bias and may not fully correspond to actual behavior or objective proficiency. Incorporating performance-based assessments, behavioral tasks, or multimodal measures would help validate and extend the present findings.

Fourth, the cross-sectional design restricts interpretation to correlational relationships. Because all variables were measured at a single time point, it is not possible to infer causal pathways between AI risk perception and adoption willingness, nor to examine how these perceptions evolve as students progress through their academic programs or gain professional experience. Longitudinal or repeated-measures studies would allow for analysis of developmental trajectories and provide stronger evidence on the impact of educational interventions.

These limitations highlight the need for cautious interpretation of the findings and indicate clear opportunities for future research to build on and expand the present work.

6. Conclusion

As AI technologies become increasingly integrated into society, understanding how future professionals evaluate AI-related risks is essential. This study examined technology students' explicit and scenario-based AI risk awareness, their adoption willingness across application domains, and the influence of gender and disciplinary background on these judgments.

Four consistent patterns emerged. First, students expressed substantially stronger concern for explicitly stated AI risks than for the same risks embedded in realistic scenarios, indicating that abstract knowledge does not readily translate into contextual risk recognition. Second, adoption willingness declined systematically as perceived contextual risk increased, demonstrating that students' acceptance of AI systems is closely tied to their appraisal of domain-specific risks. Third, although technical training appeared to equalize gender differences in risk awareness, male students consistently reported higher willingness to adopt AI technologies, revealing a behavioral gap not explained by differences in evaluative judgment. Fourth, students in AI-intensive majors such as Computer Science and Data Science showed both higher explicit risk awareness and higher adoption willingness than their non-technical peers—a pattern consistent with the form of “risk underappreciation” in which technical familiarity coexists with reduced caution in applied contexts.

Together, these findings show that technology students' engagement with AI is shaped by both how risks are framed and who is evaluating them. Strengthening responsible AI practice will therefore require educational approaches that pair explicit instruction with scenario-based reasoning, address behavioral and psychological dimensions of adoption, and support more calibrated decision-making across disciplinary groups. Such efforts will be critical as AI continues to expand across academic and professional environments.
